PROBITY DOCUMENT

CERTIFIED COPY OF

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay, please contact the Patent Office.

Patents Form 1/77

VALUE TRANSACTION SYSTEMS

This invention relates to value transaction systems, and is particularly but not exclusively concerned with transaction systems for providing products or tickets or the like in exchange for value, preferably in an unattended and/or
5 offline situation. The invention is further concerned with systems comprising interconnected transaction units such as coin mechanisms, banknote mechanisms, card readers, vending machines, etc.

It is well known to interconnect various units in order to form a
10 transaction system, for example, to fit a card reader into a vending machine. To facilitate this, there are various standards which permit interconnection of transaction units. The units must be configured to allow intercommunication using the selected common hardware and software standards. It would be desirable to make this operation easier, and also to introduce more flexibility
15 into the way in which the different units of the transaction system interact. It would also be desirable to reduce the cost of transaction systems, and simplify changes, upgrades and servicing of the system.

Aspects of the invention are set out in the accompanying claims.

In the preferred embodiments described below, a transaction system
20 comprises a plurality of transaction units including one or more of the following: a coin validator, a banknote validator, a card reader, a vending machine. A single controller, which may be housed in one of the transaction

units, is capable of controlling all the interconnected units. To achieve this, the controller has an operating system and a memory storing several units of executable code. (In the following, the term "unit" is used to refer not only to a hardware device - that is, a transaction unit - preferably forming a discrete
5 but connected part of the system, but also to a collection of software routines - that is, a code unit - which may, for example, control such a hardware unit.)

A first unit of code handles the low-level operation of the transaction unit in which the code is stored; for example, in a coin or banknote validator it would handle the reading of the sensors and the processing of the outputs
10 thereof to determine coin or banknote validity. This may be native, and preferably compiled, code. A second unit of code is divided into a plurality of sub-units. One of these may be a central transaction control module for authorising transactions carried out by the transaction units. The others may each be dedicated to controlling higher-level tasks of the respective
15 transaction units.

Preferably, the sub-units store executable code in the form of Java bytecodes, and the controller has a Java Virtual Machine (JVM) which issues instructions to the operating system in response to execution of the Java bytecodes. Preferably the first unit and each of the sub-units of code are in
20 respective protected memory areas.

By using such a system, it is possible for the transaction units to be inexpensive, as they have to handle only low-level tasks, due to the use of a

common controller for performing the high-level tasks. Because the high-level tasks are performed in a common control unit, exchange of information between the tasks is rendered simpler, and no longer dependent upon the way in which the units are interconnected. It is therefore possible to use a simple,
5 common hardware and software standard for the interconnection, for example an interconnection complying with the Universal Serial Bus standard.

It is particularly desirable for the controller to have a run-time interpreter, such as a JVM, for executing program code stored in non-volatile semiconductor memory. The interpreter can ensure that no illegal operations
10 are carried out by the code at run-time, and thus enforce security. Accordingly, this encourages the design of systems which allow for third-party supply of software.

There may be numerous functions which are carried out by the individual transaction units under the control of signals from the controller.
15 Also, there may be numerous types of messages sent by the transaction units to the controller. In order to facilitate this, the signals delivered to and from the transaction units preferably comply with a simple protocol, which includes (a) an identifying code or address for identifying the relevant transaction unit, (b) a function code identifying the function or command to be carried out by
20 the transaction unit or the event being reported on by the unit, and optionally (c) a parameter for use by the transaction units in carrying out the command, or for describing a reported event.

Arrangements embodying the invention will now be described by way of example with reference to the accompanying drawings, in which:

Figure 1 illustrates a transaction system in accordance with the invention;

5 Figure 2 shows the configuration of a controller housed within a coin changer of the transaction system of Figure 1; and

Figure 3 shows a second transaction system in accordance with the invention.

Referring to Figure 1, a transaction system 2 comprises units 4, 6, 8
10 and 10, all interconnected by a single bus 12, which in this embodiment is a Universal Serial Bus (USB).

The transaction unit 4 is a coin changer, which includes the necessary components for receiving, validating, storing and dispensing coins. The coin
changer 4 has a unit interface 14 for sending and receiving signals along the
15 USB 12. The coin changer 4 preferably includes a plurality of coin stores for storing respective coin denominations for change payout purposes. When a serviceman visits the machine, the levels in each tube can be brought to a respective predetermined float level. The coin changer 4 has a procedure for facilitating this by causing, in a float mode, all inserted coins of a respective
20 denomination to be delivered to an appropriate change store until the float level is reached, after which further coins are rejected. Also, the changer can

be controlled so as to dispense coins from a coin store until the float level is reached.

The transaction unit 6 is a banknote validator containing the necessary components for receiving, storing and dispensing banknotes, and also includes
5 a unit interface 14 similar to that of the coin changer 4.

The transaction unit 8 is a card reader also containing an interface 14. The card reader 8 is operable to receive information from and write information to smart cards containing electronic memory circuits and/or processors. The card reader 8 may additionally be able to read and write
10 magnetic cards, or there may be another unit for performing this function.

The transaction unit 10 is a vending machine controller containing an interface 14. This is housed in a vending machine (not shown) and enables the vending of products in response to signals received along the USB 12. The other units 4, 6 and 8 may also be housed in the vending machine.

15 The coin mechanism unit 4 also houses a system controller 16. The controller is operable to control the operation of each of the units 4, 6, 8 and 10. It could be housed in any of the other units, but it is preferred that it be housed in the coin mechanism unit 4, because although each of the units is optional within a transaction system, a coin mechanism is likely to be
20 required, and because the coin mechanism (and the banknote mechanism 6) perform the most processor-intensive tasks.

Referring to Figure 2, the system controller 16 is shown schematically. This comprises a processor 18 which includes a read/write memory (not shown) acting as a scratchpad memory. The processor 18, which may be a readily-available standard microprocessor, is coupled to memory means
5 storing code in code units 20, 22, 24, 26, 28, 30, 32, 34, 35 and 36.

The microprocessor 18 performs instructions under the control of a real-time operating system formed by code unit 20. The operating system 20 is a multi-tasking operating system which in this embodiment executes code in the code units 22, 24 and 26.

10 The code unit 22 performs low-level validation tasks, including taking readings from the sensors (not shown) of the coin mechanism and checking these against acceptance criteria. The code in unit 22 may be legacy code, i.e. code which has been used in prior art validators. For speed and compactness, the code is preferably native, and more preferably compiled, code.

15 The code unit 24 performs housekeeping tasks, including enabling communication with the interface 14. The code unit 26 is a Java Virtual Machine.

High-level operations of the transaction units 4, 6, 8 and 14 are performed by the Java Virtual Machine 26, under the control of respective
20 code units 28, 30, 32 and 34. A further code unit 35 handles overall transaction control and authorisation. Each of these units 28 to 35 stores executable code in the form of Java bytecodes. To facilitate the writing of this

code, and for the sake of efficiency, the controller unit 16 also has a further code unit 36, which implements an Application Programmer Interface (API), and which also consists of Java bytecodes. The code of this unit 36 represents Java classes which can be used by the various units 28 to 35.

5 Each of the code units 28, 30, 32, 34 and 35 forms a respective code module which is independently functional without regard to the presence of any other code module. (The transaction code module 35 receives signals from and send signals to the other modules, according to a predetermined protocol; thus, the operations of the module may depend on operations
10 performed by other modules. However, each module can perform its functions without relying on code in any other module.) Each module is in a respective, protected memory area (as are, preferably, the code units 22 and 24). Because of this, and because of aspects of the Java language discussed below, it is not possible for any of the applications within the respective
15 modules to interfere with any of the other applications. The memory areas may be protected in any of a number of different ways. For example, they could be "write-once" memories which cannot be altered after the software has been loaded. Alternatively, they could be hardware protected, so that physical memory addresses are checked by dedicated circuitry to ensure
20 access is provided only to appropriate software (e.g. software in the respective area). Alternatively, the operating system 20 could perform a corresponding task.

Accordingly, such an arrangement is particularly suited for enabling various different manufacturers to produce individual transaction system units and/or the controlling code for such units, using simple and standard hardware and software, without any significant risk of this interfering with the operation
5 of other transaction units even if the system contains transaction units from different manufacturers.

The functions performed by the software modules 28 to 35 may include the following:

Transaction Code Module 35

10 This would receive credit signals from the coin changer 4, banknote validator 6 and card reader 8, and product selection information (such as a product price) from the vending machine controller 10, preferably via their respective controlling modules. The transaction controller would compare credits with prices, and when appropriate would issue an authorisation signal
15 to the code module 34 for the vending machine controller 10 for permitting a vend. The module would also issue signals to the code modules for the coin changer 4, the banknote validator 6 and card reader 8 indicating that a vend has taken place. This would enable the dispensing of change from the coin changer 4 and/or banknote validator 6 (and for this purpose the transaction
20 controller may provide signals indicating how much change is to be dispensed) under the control of their respective code modules, and/or would instruct the code module for the card reader 8 to write a new credit amount on

the card (which would occur before sending the vend authorisation signal to the vend controller 10).

The transaction module 35 would also be arranged to perform audit functions, i.e. to keep a record of transactions carried out by the various transaction units and to make this record available for downloading, for
5 example to a terminal temporarily connected to the transaction system, or remotely via, for example, a telephone line.

Coin Changer Code Module 28

This module receives signals indicative of acceptable coins from the
10 code unit 22. For code portability, the code unit 22 may deliver the signals via the transaction module 35 and/or the interface 14, so the same module 28 can be used in other systems in which it is not held within the coin changer unit 4. The code module 28 also forwards signals representing an amount of credit to the transaction code module 35. The module 28 may also contain an
15 algorithm for calculating the distribution of denominations to be paid out in change, on receipt of the signal from the transaction module indicating how much change should be dispensed. For this purpose, the module may be arranged to receive from the coin changer 4 signals representing how much change is available in the respective denominations stored by the changer.

20 The module 28 may also be used to determine the above-mentioned "float levels".

The module may also issue signals to the coin changer 4 for selectively inhibiting acceptance of particular denominations.

Banknote Validator Module 30

5 This may be arranged to perform for the banknote validator the same functions as the module 28 performs for the coin changer 4.

Card Reader Module 32

10 This module may be arranged to process data received from the card reader in order to determine credit values which are then passed to the transaction module 35. Similarly, any debit instructions issued by the module 35 may be interpreted by the card reader module 32 before being passed on to the card reader itself.

15 In addition, the module 32 may be arranged to respond to signals from the card reader in order to deduce the type and/or functionality of the card which has been inserted, and then issue appropriate instructions to the card reader. Thus, this enables automatic adaptation so that, for example, the appropriate protocol is used for communicating with the inserted card, or the appropriate operations are carried out depending on whether the card is a debit card or a credit card, etc.

20 In order to deal with different types of cards, the module 32 may itself comprise sub-modules (as indicated by broken lines), each possibly in its own protected memory area, and each handling a respective application for a

respective type of card. The application can be selected in accordance with the detected protocol.

Vending Machine Control Module 34

5 This would receive product selection signals from the vending machine controller 14, send product price values to the transaction controller module 35, receive therefrom the vend authorisation signal and send a product dispense signal to the controller 10.

10 The module 34 may also be arranged to send to the vending machine controller 10 signals representing messages to be displayed on a display of the vending machine.

In a preferred embodiment, the units 6, 8 and 10 may each have a respective memory storing the bytecodes for the respective modules 30, 32 and 34. The contents of the memory in each unit are uploaded to the system controller 16 in an initialisation operation for that unit.

15 In an alternative embodiment, the JVM 26 is replaced by a just-in-time (JIT) compiler.

In a further alternative, the JVM 26, the operating system 20 and the processor 18 are replaced by a Java Physical Machine (JPM), in which case the codes in modules 22 and 24 are also formed by Java bytecodes.

20 Figure 3 represents an alternative embodiment of the transaction system 2, in which the system controller 16 is housed in a separate controller unit 38, instead of one of the transaction units 4, 6, 8 and 10.

It is possible to use languages other than Java for the modules 28, 30, 32, 34 and 35. However, whichever language is used, it is preferable that this be an interpreted language so that restrictions can be enforced at run time to ensure integrity.

5 In particular, it is preferable that the language incorporate restrictions so as to prevent direct access to physical addresses. Thus, it is desirable to ensure that the language does not use pointers explicitly. It is also preferable that the language be such that array accesses are checked to be within bounds at run-time, that only legal type conversions are allowable and that all method
10 calls are checked to ensure that the method is being invoked on the correct type of object.

Also, it is possible for one or more of the individual modules to include, or be formed by, native or compiled code, although this would obviate some of the advantages mentioned above. For example, the module
15 28 could be omitted, and the functions performed instead by the code in unit 27.

It is also desirable for there to be an authentication procedure, such that the software of each module is run only if the JVM determines, according to a predetermined set of conditions, that the software is authentic. For
20 example, the software could contain an authentication code which has to be deemed by the interpreter to be appropriate before the software is run.

It may also be possible to have a conventional transaction unit, with its own controlling software, coupled to a system according to the invention.

Java is a trademark of Sun Microsystems, Inc.

CLAIMS:

1. A value transaction system comprising a plurality of transaction units and a controller having a processor and memory means
5 storing run-time interpreted code units each associated with a respective transaction unit, the controller being operable to execute the code of each respective code unit and in response thereto to generate signals controlling the operation of the respective transaction units.

10 2. A system as claimed in claim 1, further comprising a native code unit operable to accept and process input signals for the purpose of validation of an item of money.

3. A system as claimed in claim 1 or claim 2, wherein the
15 transaction units are arranged to handle respective types of payment media.

4. A system as claimed in any preceding claim, wherein each interpreted code unit is independently functional without regard to the presence of the other interpreted code units.

20

5. A system as claimed in claim 4, including an API code unit containing routines which are accessible at run-time by each of the interpreted code modules.

5 6. A system as claimed in any preceding claim, wherein the memory means is a non-volatile semiconductor memory.

7. A transaction unit having a microprocessor system including:

- 10 (a) a validation code unit operable to accept and process input signals for the purposes of validation of an item of money;
- (b) a Java Virtual Machine; and
- (c) at least one Java application operable to perform controlling functions for a respective further transaction unit to which the first-mentioned transaction unit is connected.

15

8. A transaction unit as claimed in claim 7, wherein the validation code unit comprises native code.

9. A transaction unit as claimed in claim 7 or 8, wherein the
20 validation code unit comprises compiled code.

10. A transaction unit as claimed in claim 7, 8 or 9, including a further Java application operable to perform controlling functions for the first-mentioned transaction unit.

5 11. A transaction unit as claimed in any one of claims 7 to 10, wherein the transaction unit is a coin validation mechanism.

12. A transaction system comprising a transaction unit as claimed in any one of claims 7 to 11, and at least one further transaction unit under the control of the microprocessor system in said first-mentioned transaction unit.

13. A transaction system as claimed in claim 12, wherein the transaction units are interconnected via a serial link.

15 14. A transaction system comprising:
a plurality of transaction units; and
a controller having a processor and memory means storing executable code in respective code modules each associated with a respective one of the transaction units, the controller being coupled to the transaction units and
20 arranged to receive and send signals from and to the transaction units;
the controller being operable to execute the code in each respective code module, the code in that module being functional independently of the

code in the other modules and performing processing operations in response to signals received from its respective transaction unit indicative of respective operations performed by that transaction unit, and the code being further operable to cause the controller to generate controlling signals for sending to the respective transaction unit and capable of representing different functions to be performed by the transaction unit.

15. A transaction system as claimed in claim 14, wherein the memory means has executable code in a further code module, that executable code being responsive to credit-representing signals generated by the code in one or more other code modules, and being operable to produce vend-authorising signals for use by the executable code in at least one other code module.

16. A transaction system as claimed in claim 14 or claim 15, wherein the executable code is run-time interpreted code.

17. A transaction system as claimed in any one of claims 14 to 16, wherein the controller is housed in one of the transaction units.

18. A transaction system as claimed in any one of claims 14 to 17, wherein each code module is contained in a respective area of protected memory.

5 19. A transaction system as claimed in any one of claims 14 to 18, wherein the executable code is Java bytecode.

20. A transaction system as claimed in any one of claims 14 to 19, wherein the transaction units are interconnected via a serial link.

10

21. A transaction system as claimed in any one of claims 14 to 20, wherein the transaction units include one or more of (a) a coin mechanism unit, (b) a banknote mechanism unit, (c) a card reader unit and (d) a vending machine controller unit.

15

22. A transaction system comprising a controller unit including a processor operable to execute instructions in Java code, and at least one transaction unit including means for performing value transactions under the control of the processor executing code uploaded from the transaction unit.

20

23. A transaction system as claimed in claim 22, wherein the transaction system comprises a plurality of transaction units, and the

controller unit is operable to execute code stored in respective code units each associated with a respective transaction unit.

24. A transaction system as claimed in claim 23, wherein the code
5 units are stored in respective protected memory areas.

25. A method of assembling a transaction system, the transaction
system comprising a plurality of transaction units and a controller having a
processor and memory means for storing executable code in respective code
10 modules each associated with a respective one of the transaction units, the
controller being coupled to the transaction units and arranged to receive and
send signals from and to the transaction units, and the controller being
operable to execute the code in each respective code module, each code
module performing processing operations in response to signals received from
15 the respective transaction unit indicative of respective operations performed
by that transaction unit, and the code module being further operable to cause
the controller to generate controlling signals for sending to the respective
transaction unit and capable of representing different functions to be
performed by the transaction unit; the method comprising:

20 separately loading the executable code for the respective code modules
into the memory means of the controller.

23. A transaction system substantially as herein described with reference to Figures 1 and 2, or Figures 2 and 3, of the accompanying drawings.

ABSTRACT

A transaction system comprises a plurality of transaction units each for performing a respective type of transaction. The units are interconnected via a serial link, and there is a common controller which has respective protected
5 memory areas storing Java code for controlling the respective units.
